1 Introduction

Given sets $X, Y$ and $P \subseteq X \times Y$ with $\text{proj}_X(P) = X$, a uniformization of $P$ is a function $f: X \to Y$ such that $\forall x \in X ((x, f(x)) \in P)$. If now $E$ is an equivalence relation on $X$, we say that $P$ is $E$-invariant if $x_1 E x_2 \implies P_{x_1} = P_{x_2}$, where $P_x = \{y: (x, y) \in P\}$ is the $x$-section of $P$. Equivalently this means that $P$ is invariant under the equivalence relation $E \times \Delta_Y$ on $X \times Y$, where $\Delta_Y$ is the equality relation on $Y$. In this case an $E$-invariant uniformization is a uniformization $f$ such that $x_1 E x_2 \implies f(x_1) = f(x_2)$.

Also if $E, F$ are equivalence relations on sets $X, Y$, resp., a homomorphism of $E$ to $F$ is a function $f: X \to Y$ such that $x_1 E x_2 \implies f(x_1) F f(x_2)$. Thus an invariant uniformization is a uniformization that is a homomorphism of $E$ to $\Delta_Y$.

Consider now the situation where $X, Y$ are Polish spaces and $P$ is a Borel subset of $X \times Y$. In this case standard results in descriptive set theory provide conditions which imply the existence of Borel uniformizations. These fall mainly into two categories, see [K1, Section 18]: “small section” and “large section” uniformization results. We will concentrate here on the following standard instances of these results:

**Theorem 1.1** (Measure uniformization). Let $X, Y$ be Polish spaces, $\mu$ a probability Borel measure on $Y$ and $P \subseteq X \times Y$ a Borel set such that $\forall x \in X (\mu(P_x) > 0)$. Then $P$ admits a Borel uniformization.

**Theorem 1.2** (Category uniformization). Let $X, Y$ be Polish spaces and $P \subseteq X \times Y$ a Borel set such that $\forall x \in X (P_x$ is non-meager). Then $P$ admits a Borel uniformization.
Theorem 1.3 \textbf{(}${\mathcal K}_\sigma$\textbf{ uniformization)}. \textit{Let $X,Y$ be Polish spaces and $P \subseteq X \times Y$ a Borel set such that $\forall x \in X(P_x$ is non-empty and $K_\sigma$). Then $P$ admits a Borel uniformization.}

A special case of Theorem 1.3 is the following:

Theorem 1.4 \textbf{(Countable uniformization)}. \textit{Let $X,Y$ be Polish spaces and $P \subseteq X \times Y$ a Borel set such that $\forall x \in X(P_x$ is non empty and countable). Then $P$ admits a Borel uniformization.}

Suppose now that $E$ is a Borel equivalence relation on $X$ and $P$ in any one of these results is $E$-invariant. When does there exist a Borel $E$-invariant uniformization, i.e., a Borel uniformization that is also a homomorphism of $E$ to $\Delta_Y$? We say that $E$ satisfies \textbf{measure (resp., category, ${\mathcal K}_\sigma$, countable) invariant uniformization} if for every $Y,\mu,P$ as in the corresponding uniformization theorem above, if $P$ is moreover $E$-invariant, then it admits a Borel $E$-invariant uniformization.

The following gives a complete answer to this question. Recall that a Borel equivalence relation $E$ on $X$ is \textbf{smooth} if there is a Polish space $Z$ and a Borel function $S: X \to Z$ such that $x_1 Ex_2 \iff S(x_1) = S(x_2)$.

\textbf{Theorem 1.5.} \textit{Let $E$ be a Borel equivalence relation on a Polish space $X$. Then the following are equivalent:

(i) $E$ is smooth;

(ii) $E$ satisfies measure invariant uniformization;

(iii) $E$ satisfies category invariant uniformization;

(iv) $E$ satisfies $K_\sigma$ invariant uniformization.

(v) $E$ satisfies countable invariant uniformization.}

The equivalence of (i) and (v) in Theorem 1.5 essentially reduces to the fact that if $E$ is a countable Borel equivalence relation (i.e., one all of which equivalence classes are countable) which is not smooth, then the relation

$$(x,y) \in P \iff xEy,$$

is clearly $E$-invariant with countable nonempty sections but has no $E$-invariant uniformization. Recently Miller [Mi] proved the following dichotomy that shows that this is essentially the only obstruction to (v). Below $E_0$ is the non-smooth Borel equivalence relation on $2^\mathbb{N}$ given by $xE_0y \iff \exists m \forall n \geq m(x_n = y_n)$ and $E_0 \times I_\mathbb{N}$ is the equivalence relation on $2^\mathbb{N} \times \mathbb{N}$ given by
(x, m)E_0 \times I_\mathbb{N}(y, n) \iff \pi(x_1)F_{\pi}(x_2).

**Theorem 1.6** ([Mi, Theorem 2]). Let X, Y be Polish spaces, E a Borel equivalence relation on X and P \subseteq X \times Y an E-invariant Borel relation with countable non-empty sections. Then exactly one of the following holds:

1. There is a Borel E-invariant uniformization,
2. There is a continuous embedding \( \pi_X : 2^\mathbb{N} \times \mathbb{N} \to X \) of \( E_0 \times I_\mathbb{N} \) into E and a continuous injection \( \pi_Y : 2^\mathbb{N} \times \mathbb{N} \to Y \) such that \( P \cap (\pi_X(2^\mathbb{N} \times \mathbb{N})) \times Y = (\pi_X \times \pi_Y)(E_0 \times I_\mathbb{N}). \)

It would be interesting to find a dichotomy that determines the obstructions to (ii)-(iv).

We next consider a somewhat less strict notion of invariant uniformization, where instead of selecting a single point in each section we select a countable nonempty subset. More precisely, given Polish spaces X, Y, a Borel equivalence relation E on X and an E-invariant Borel set P \subseteq X \times Y, with proj_X(P) = X, a Borel **E-invariant countable uniformization** is a Borel function f : X \to Y^\mathbb{N} such that \( \forall x \in X \forall n \in \mathbb{N} ((x, f(x)_n) \in P) \) and \( x_1Ex_2 \iff \{f(x_1)_n : n \in \mathbb{N}\} = \{f(x_2)_n : n \in \mathbb{N}\}. \) Equivalently, if for each Polish space Y, we denote by \( E_Y^{\text{ctble}} \) the equivalence relation on \( Y^\mathbb{N} \) given by

\[
(x_n)E_Y^{\text{ctble}}(y_n) \iff \{x_n : n \in \mathbb{N}\} = \{y_n : n \in \mathbb{N}\},
\]

then an E-invariant countable uniformization is a Borel homomorphism f of E to \( E_Y^{\text{ctble}} \) such that for each x, n, we have that \((x, f(x)_n) \in P\).

We say that E satisfies **measure (resp., category, K_\sigma)** countable invariant uniformization if for every Y, \( \mu, P \) as in the corresponding uniformization theorem above, if \( P \) is moreover E-invariant, then it admits a Borel E-invariant countable uniformization.

Recall that a Borel equivalence relation E on X is **reducible to countable** if there is a Polish space Z, a countable (i.e., having all classes countable) Borel equivalence relation F on Y and a Borel function S : X \to Z such that \( x_1Ex_2 \iff S(x_1)FS(x_2). \)

As in the proof of Theorem 1.5, one can see that if a Borel equivalence relation E on X is reducible to countable, then E satisfies measure (resp. category, K_\sigma) countable invariant uniformization. We conjecture the following:
Conjecture 1.7. Let $E$ be a Borel equivalence relation on a Polish space $X$. Then the following are equivalent:
(a) $E$ is reducible to countable;
(b) $E$ satisfies measure countable invariant uniformization;
(c) $E$ satisfies category countable invariant uniformization;
(d) $E$ satisfies $K_\sigma$ countable invariant uniformization.

We discuss some partial results in Section 3.

Acknowledgment. Research partially supported by NSF Grant DMS-1950475. I would like to thank Todor Tsankov who asked me whether measure invariant uniformization holds for countable Borel equivalence relations.

2 Proof of Theorem 1.5

(A) We first show that (i) implies (ii), the proof that (i) implies (iii) being similar. Fix a Polish space $Z$ and a Borel function $S: X \to Z$ such that $x_1Ex_2 \iff S(x_1) = S(x_2)$. Fix also $Y, \mu, P$ as in the definition of measure invariant uniformization. Define $P^* \subseteq Z \times Y$ as follows:

$$(z, y) \in P^* \iff \forall x \in X (S(x) = z \implies (x, y) \in P).$$

Then $P^*$ is $\Pi_1^1$ and we have that

$$S(x) = z \implies P^*_z = P_x,$$
$$z \notin S(X) \implies P^*_z = Y.$$

Thus $\forall z \in Z(\mu(P^*_z) > 0)$. Then, by [K1, 36.24], there is a Borel function $f^*: Z \to Y$ such that $\forall z \in Z((z, f^*(z)) \in P^*)$. Put

$$f(x) = f^*(S(x)).$$

Then $f$ is an $E$-invariant uniformization of $P$.

We next prove that (i) implies (iv) (and therefore (v)). Fix $Z, S$ as in the previous case and $Y, P$ as in the definition of $K_\sigma$ invariant uniformization. Define $P^*$ as before. Let $\varphi: P^* \to \omega_1$ be a $\Pi_1^1$-rank. Then $A = \{(z, y): z \in S(X), (z, y) \in P\}$ is a $\Sigma_1^1$ subset of $P^*$, so, by boundedness, there is a countable ordinal $\alpha$ such that $\forall (z, y) \in A(\varphi(z, y) < \alpha)$. Therefore there is a Borel subset $P^{**}$ of $P^*$ such that $A \subseteq P^{**}$. By [K1, 35.47], the set $C$ of
all $z \in Z$ such that $P_z^{**}$ is $K_\sigma$ is $\Pi^1_1$ and contains the $\Sigma^1_1$ set $S(X)$, so by separation there is a Borel set $B$ with $A \subseteq B \subseteq C$. Then if $Q \subseteq Z \times Y$ is defined by

$$(z, y) \in Q \iff z \in B \& (z, y) \in P^{**},$$

we have that

$$S(x) = z \implies Q_z = P_x,$$

and every $Q_z$ is $K_\sigma$. It follows, by [K1, 35.46], that $D = \text{proj}_Z(Q)$ is Borel and there is a Borel function $g: D \rightarrow Y$ such that $\forall z \in D(z, g(z)) \in Q$. Since $f(X) \subseteq D$, the function

$$f(x) = g(S(x)).$$

is an $E$-invariant uniformization of $P$.

(B) We will next show that $\neg${(i)} implies $\neg${(ii)}, $\neg${(iii)} and $\neg${(v)} (and thus also $\neg${(iv)}). We will use the following lemma. Below for Borel equivalence relations $E, E'$ on Polish spaces $X, X'$, resp., we write $E \leq_B E'$ iff there is a Borel map $f: X \rightarrow X'$ such that $x_1 E x_2 \iff f(x_1) E' f(x_2)$, i.e., $E$ can be Borel reduced to $E'$ (via the reduction $f$).

Lemma 2.1. Let $E, F$ be Borel equivalence relations on Polish spaces $X, X'$, resp., such that $E \leq_B E'$. If $E$ fails (ii) (resp., (iii), (iv), (v)), so does $E'$.

Proof. Let $f: X \rightarrow X'$ be a Borel reduction of $E$ into $E'$. Assume first that $E$ fails (ii) with witness $Y, \mu, P$. Define $P' \subseteq X' \times Y$ by

$$(x', y) \in P' \iff \forall x \in X \left(f(x) E' x' \implies (x, y) \in P\right).$$

Then note that

$$f(x) E' x' \implies P'_{x'} = P_x,$$

$$x' \notin [f(X)]_{E'} \implies P'_{x'} = Y.$$

Now clearly $P'$ is $\Pi^1_1$ and invariant under the Borel equivalence relation $E' \times \Delta_Y$. Then by a result of Solovay (see [K1, 34.6]), there is a $\Pi^1_1$-rank $\varphi: P' \rightarrow \omega_1$ which is $E' \times \Delta_Y$-invariant. Consider then the $\Sigma^1_1$ subset $P''$ of $P'$ defined by:

$$(x', y) \in P'' \iff \exists x \in X \left(f(x) E' x' \& (x, y) \in P\right).$$
By boundedness there is a Borel $E' \times \Delta_Y$-invariant set $P'''$ with $P'' \subseteq P''' \subseteq P'$. Let now $Z \subseteq X'$ be defined by

$$x' \in Z \iff \mu(P_{x'}''') > 0.$$ 

Then $Z$ is Borel and $E'$-invariant and contains $[f(X)]_{E'}$. Finally define $Q \subseteq X' \times Y$ by

$$(x', y) \in Q \iff (x' \in Z \& (x', y) \in P''') \text{ or } x' \notin Z.$$ 

Then $f(x) = x' \implies Q_{x'} = P_x$, so $Y, \mu, Q$ witnesses the failure of (ii) for $E'$.

The case of (iii) is similar and we next consider the case of (iv). Repeat then the previous argument for case (ii) until the definition of $P'''$. Then define $Z' \subseteq X'$ by

$$x' \in Z' \iff P_{x'}''' \text{ is } K_\sigma \text{ and nonempty.}$$ 

Then $Z'$ is $\mathbf{P}_1$ by [K1, 35.47] and the relativization of the fact that every nonempty $\Delta^1_1$ $K_\sigma$ set contains a $\Delta^1_1$ member, see [M, 4F.15]. It is also $E'$-invariant and contains $[f(X)]_{E'}$. Let then $Z$ be $E'$-invariant Borel with $[f(X)]_{E'} \subseteq Z \subseteq Z'$ and define $Q$ as before but replacing “$x' \notin Z$” by “$(x \notin Z \text{ and } y = y_0)$”, for some fixed $y_0 \in Y$. Then $Y, Q$ witnesses the failure of (iv) for $E'$.

Finally, the case of (v) is similar to (iv) by now defining

$$x' \in Z' \iff P_{x'}''' \text{ is countable and nonempty.}$$ 

and using that $Z'$ is $\mathbf{P}_1$ by [K1, 35.38] (and [M, 4F.15] again). $\square$

Assume now that $E$ is not smooth. Then by [HKL] we have $E_0 \leq_B E$. Thus by Lemma 2.1 it is enough to show that $E_0$ fails (ii), (iii), and (v) (thus also (iv)).

We first prove that $E_0$ fails (ii). We view here $2^\mathbb{N}$ as the Cantor group $(\mathbb{Z}/2\mathbb{Z})^\mathbb{N}$ with pointwise addition $+$ and we let $\mu$ be the Haar measure, i.e., the usual product measure. Let then $A \subseteq (\mathbb{Z}/2\mathbb{Z})^\mathbb{N}$ be an $F_\sigma$ set which has $\mu$-measure 1 but is meager. Let $X = Y = (\mathbb{Z}/2\mathbb{Z})^\mathbb{N}$ and define $P \subseteq X \times Y$ as follows:

$$(x, y) \in P \iff \exists x' E_0 x(x' + y \in A).$$ 

Clearly $P$ is $F_\sigma$ and, since $P_x = \bigcup_{x' \in E_0 x} (A - x')$, clearly $\mu(P_x) = 1$. Moreover $P$ is $E_0$-invariant. Assume then, towards a contradiction that $f$ is a Borel
$E_0$-invariant uniformization. Since $x E_0 x' \implies f(x) = f(x')$, by generic ergodicity of $E_0$ there is a comeager Borel $E_0$-invariant set $C \subseteq X$ and $y_0$ such that $\forall x \in C(f(x) = y_0)$, thus $\forall x \in C(x, y_0) \in P$, so $\forall x \in C \exists x' E_0 x (x' \in A - y_0)$. If $G \subseteq (\mathbb{Z}/2\mathbb{Z})^N$ is the subgroup consisting of the eventually 0 sequences, then $x E_0 y \iff \exists g \in G(g + x = y)$, thus $C = \bigcup_{g \in G}(g + (A - y_0))$, so $C$ is meager, a contradiction.

To show that $E_0$ fails (v), define

$$(x, y) \in P \iff x E_0 y.$$ 

Then any Borel $E_0$-invariant uniformization of $P$ gives a Borel selector for $E_0$, a contradiction.

Finally to see that $E_0$ fails (iii), use above $B = (\mathbb{Z}/2\mathbb{Z})^N \setminus A$, instead of $A$, to produce a $G_\delta$ set $Q$ as follows:

$$(x, y) \in Q \iff \forall x' E_0 x (x' + y \in B).$$

Then $Q$ is $E_0$-invariant and has comeager sections. If $g$ is a Borel $E_0$-invariant uniformization, then by the ergodicity of $E_0$, there is a $\mu$-measure 1 set $D$ and $y_0$ such that $\forall x \in D \forall x' E_0 x (x' \in B - y_0)$, so $D \subseteq B - y_0$, thus $\mu(D) = 0$, a contradiction.

This completes the proof of Theorem 1.5.

(C) The following is an open problem:

**Problem 2.2.** Is there a Polish space $Y$, probability Borel measure $\mu$ on $Y$ and a $G_\delta$ set $P \subseteq 2^N \times Y$ (or even a Borel set $P \subseteq 2^N \times Y$ with $G_\delta$ sections) with $\mu(P_x) > 0$, which is $E_0$-invariant but admits no Borel $E_0$-invariant uniformization? Similarly, is there a Polish space $Y$ and an $F_\sigma$ set $Q \subseteq 2^N \times Y$ (or even a Borel set $Q \subseteq 2^N \times Y$ with $F_\sigma$ sections) with $\mu(Q_x)$ non-meager, which is $E_0$-invariant but admits no Borel $E_0$-invariant uniformization?

## 3 On Conjecture 1.7

Concerning Conjecture 1.7, we first note the following analog of Lemma 2.1.

**Lemma 3.1.** Let $E, F$ be Borel equivalence relations on Polish spaces $X, X'$, resp., such that $E \leq_B E'$. If $E$ fails (b) (resp., (c), (d)), so does $E'$.
The proof is identical to that of Lemma 2.1. Note now that any countable Borel equivalence relation $E$ trivially satisfies (b), (c), and (d), so by Lemma 3.1, in Conjecture 1.7, (a) implies (b), (c) and (d).

To verify then Conjecture 1.7, one needs to show that if $E$ is not reducible to countable, then (b), (c) and (d) fail. It is an open problem (see [HK, end of Section 6]) whether the following holds:

**Problem 3.2.** Let $E$ be a Borel equivalence relation which is not reducible to countable. Then one of the following holds:

1. $E_1 \leq_B E$, where $E_1$ is the following equivalence relation on $(2^\mathbb{N})^\mathbb{N}$:
   \[
   x E_1 y \iff \exists m \forall n \geq m (x_n = y_n);
   \]

2. There is a Borel equivalence relation $F$ induced by a turbulent Borel action of a Polish group such that $F \leq_B E$;

3. $E_0^{\mathbb{N}} \leq_B E$, where $E_0^{\mathbb{N}}$ is the following equivalence relation on $(2^\mathbb{N})^\mathbb{N}$:
   \[
   x E_0^{\mathbb{N}} y \iff \forall n (x_n E_0 y_n).
   \]

It is therefore interesting to show that (b), (c) and (d) fail for $E_1$, $F$ as in (2) above, and $E_0^{\mathbb{N}}$. Here are then some partial results.

**Proposition 3.3.** Let $E$ be a Borel equivalence relation which is not reducible to countable but is Borel reducible to a Borel equivalence relation $F$ with $K_\sigma$ classes. Then $E$ fails (d).

**Proof.** Suppose $E, F$ live on the Polish spaces $X, Y$, resp., and let $g: X \to Y$ be a Borel reduction of $E$ to $F$. Define $P \subseteq X \times X$ as follows:

\[
(x, y) \in P \iff g(x) F y.
\]

Clearly $P$ is $E$-invariant and has $K_\sigma$ sections. Suppose then that $P$ admitted a Borel $E$-invariant countable uniformization $f: X \to Y^{\mathbb{N}}$. Then define $h: X \to X$ by $g(x) = f(x)_0$. Then by [K2, Proposition 3.7], $h$ shows that $E$ is reducible to countable, a contradiction. \(\square\)

In particular, $E_1$ and $E_2$ (as in [HK]) fail (d). Concerning (b) and (c) for $E_1$, the following is a possible example for their failure.

8
Problem 3.4. Let \( X = (2^N)^N, Y = 2^N \) and define \( P \subseteq X \times Y \) as follows:

\[
(x, y) \in P \iff \exists m \forall n \geq m (x_n \neq y),
\]

so that \( P \) is \( E_1 \)-invariant and each section \( P_x \) is co-countable, so has \( \mu \)-measure 1 (for \( \mu \) the product measure on \( Y \)) and is comeager. Is there a Borel \( E_1 \)-invariant countable uniformization of \( P \)?

One can show the following weaker result, which provides a Borel anti-diagonalization theorem for \( E_1 \).

Proposition 3.5. Let \( f: (2^N)^N \to 2^N \) be a Borel function such that \( x E_1 y \implies f(x) = f(y) \). Then there is \( x \in (2^N)^N \) such that for infinitely many \( n \), \( f(x) = x_n \).

Thus if \( X, Y, P \) are as in Problem 3.4, \( P \) does not admit a Borel \( E_1 \)-invariant uniformization.

Proof. For any nonempty countable set \( S \subseteq 2^N \) consider the product space \( S^N \) with the product topology, where \( S \) is taken to be discrete. Denote by \( E_0(S) \) the equivalence relation on \( S^N \) given by \( x E_0(S) y \iff \exists m \forall n \geq m (x_n = y_n) \). This is generically ergodic and for \( x, y \in S^N \) we have that \( x E_0(S) y \implies f(x) = f(y) \), so there is (unique) \( x_S \in 2^N \) such that \( f(x) = x_S \), for comeager many \( x \in S^N \). Clearly \( x_S \) can be computed in a Borel way given any \( x \in (2^N)^N \) with \( S = \{ x_n: n \in \mathbb{N} \} \), i.e., we have a Borel function \( F: (2^N)^N \to 2^N \) such that

\[
\{ x_n: n \in \mathbb{N} \} = \{ y_n: n \in \mathbb{N} \} = S \implies F((x_n)) = F((y_n)) = x_S.
\]

We now use the following Borel anti-diagonalization theorem of H. Friedman, see [S, Theorem 2, page 23]:

Theorem 3.6 (H. Friedman). Let \( E \) be a Borel (even analytic) equivalence relation on a Polish space \( X \). Let \( F: X^N \to X \) be a Borel function such that

\[
\{ [x_n]_E: n \in \mathbb{N} \} = \{ [y_n]_E: n \in \mathbb{N} \} \implies F((x_n)) = F((y_n)).
\]

Then there is \( x \in X^N \) and \( i \in \mathbb{N} \) such that \( F(x) E x_i \).

Applying this to \( E \) being the equality relation on \( 2^N \) and \( F \) as above, we conclude that for some \( S \), we have that \( x_S \in S \). Then for comeager many \( x \in S^N \) we have that \( x_n = x_S \), for infinitely many \( n \), and also \((x, x_S) \in P \), a contradiction. \( \square \)
In response to a question by Andrew Marks, we note the following version of Proposition 3.5 for $E_1$ restricted to injective sequences. Below $[2^N]^N$ is the Borel subset of $(2^N)^N$ consisting of injective sequences and $x \leq_T y$ means that $x$ is recursive in $y$.

**Proposition 3.7.** Let $g: [2^N]^N \to 2^N$ be a Borel function such that $xE_1y \implies g(x) = g(y)$. Then there is $y \in [2^N]^N$ such that for all $n$, $g(y) \leq_T y_n$.

**Proof.** Fix a recursive bijection $x \mapsto \langle x \rangle$ from $(2^N)^N$ to $2^N$ and for each $i \in \mathbb{N}$ let $\bar{i} \in 2^N$ be the characteristic function of $\{i\}$. Then for each $x \in (2^N)^N$ and $i \in \mathbb{N}$, put

$$\bar{x}^i = \langle i, x_i, x_{i+1}, \ldots \rangle \in 2^N.$$ 

and

$$x' = \langle \bar{x}^0, \bar{x}^1, \ldots \rangle \in [2^N]^N.$$ 

Note that $xE_1y \implies x'E_1y'$. Finally define $f: (2^N)^N \to 2^N$ by $f(x) = g(x')$. Then by Proposition 3.5, there is $x \in (2^N)^N$ such that for infinitely many $n$ we have that $f(x) = x_n$. Let $y = x'$.

If $n$ is such that $f(x) = g(y) = x_n$, then as $x_n \leq_T \bar{x}^k = y_k, \forall k \leq n$, we have that $g(y) \leq_T y_k, \forall k \leq n$. Since this happens for infinitely many $n$, we have that $g(y) \leq_T y_n$, for all $n$. \hfill \square

We do not know anything about $E_0^{2^N}$ but if we let $E_{ctble}$ be the equivalence relation $E_2^{ctble} (so that E_0^{ctble} <_B E_{ctble})$, we have:

**Proposition 3.8.** $E_{ctble}$ fails (b) and (c).

**Proof.** We will prove that $E_{ctble}$ fails (b), the proof that it also fails (c) being similar. Let $X = (2^N)^N, Y = 2^N$, let $\mu$ be the usual product measure on $Y$ and put $E = E_{ctble}$. Define $P \subseteq X \times Y$ by

$$(x, y) \in P \iff y \notin \{x_n: n \in \mathbb{N}\}.$$ 

Clearly $\mu(P_x) = 1$ and $P$ is $E$-invariant. Assume now, towards a contradiction, that there is a Borel function $f: X \to Y^N$ such that $\forall x \in X \forall n \in \mathbb{N}((x, f(x)_n) \in P)$ and $x_1Ex_2 \implies \{f(x_1)_n: n \in \mathbb{N}\} = \{f(x_2)_n: n \in \mathbb{N}\}$. Then

$$\forall x \in X(\{f(x)_n: n \in \mathbb{N}\} \cap \{x_n: n \in \mathbb{N}\} = \emptyset).$$
Define $F: X^N \to X$ as follows: Fix a bijection $(i, j) \mapsto \langle i, j \rangle$ from $\mathbb{N}^2$ to $\mathbb{N}$ and for $n \in \mathbb{N}$ put $n = \langle n_0, n_1 \rangle$. Given $x \in X^N$, define $x' \in X$ by $x'_n = (x_{n_0})_{n_1}$. Then let $F(x) = f(x')$. First notice that

$$\{[x_n]: n \in \mathbb{N}\} = \{[y_n]: n \in \mathbb{N}\} \implies F((x_n)) = F((y_n)).$$

Thus by Theorem 3.6, there is some $x \in X^N$ and $i \in \mathbb{N}$ such that $F(x)Ex_i$, i.e., $f(x')Ex_i$ or $\{f(x')_n: n \in \mathbb{N}\} = \{(x_i)_n: n \in \mathbb{N}\} = \{x'_{(i,n)}: n \in \mathbb{N}\}$. Thus $\{f(x')_n: n \in \mathbb{N}\} \cap \{x'_n: n \in \mathbb{N}\} \neq \emptyset$, a contradiction. 

Finally, we note that by the dichotomy theorem of Hjorth concerning reducibility to countable (see [H] or [K2, Theorem 3.8]), in order to prove Conjecture 1.7 for Borel equivalence relations induced by Borel actions of Polish groups, it would be sufficient to prove it for Borel equivalence relations induced by stormy such actions.
